## Laboratory exercise 4 <br> Discriminator

1Goal:
The goal is to achieve knowledge and practical experience in design of the discriminator for modern application specific modems, to get programming and debugging experience in VHDL language.

## 2 Theoretical information

The discriminator is the final part of digital data demodulators, industrial installation control loops, software radios, etc. Often it is named as a detector. Due to the input signal modulation principle, the amplitude (AM), phase(PM), amplitude-phase, or quadratur-amplitude (QAM), frequency (FM) discriminators are distinguished.

## AM discriminator

AM discriminator is usually named as an AM demodulator or detector. An AM signal can be rectified without requiring a coherent demodulator. For example, the signal can be passed through an envelope detector. The output will follow the same curve as the input baseband signal.

When the input signal is an analytical one, i.e. I +jQ, then the AM discriminator output signal is the complex vector magnitude:

$$
A=\sqrt{I^{2}+Q^{2}} .
$$

The square root function is rather complex to calculate. Therefore the direct calculation of the vector magnitude is implemented in discriminators rarely. But in many cases the output signal is enough to be calculated with the error ca $5 \%$. The French mechanician Ponselet was the first who proposed the best linear approximation of this formula in 1828.

If $\mathrm{I}>\mathrm{O}, \mathrm{Q}>\mathrm{O}, \mathrm{I}>\mathrm{Q}$, then $\mathrm{A} \approx 0.9605^{*} \mathrm{I}+0.3978^{*} \mathrm{Q}$, and
if $\mathrm{I}>2 \mathrm{Q}$, then $\mathrm{A} \approx 0.9859^{*} \mathrm{I}+0.2327^{*} \mathrm{Q}$ and so on.
In the first situation the approximation error is less than $4 \%$, and in the second one it is less than $1.4 \%$.

The coefficients can be represented by the binary code as
$0.9605 \approx 0.11110110$ and $0.3978 \approx 0.0110110$,
and they are represented by the following sums of fractions
$0.11110110=1-1 / 16+1 / 64+1 / 128$ and $0.0110110=1 / 4+1 / 8+1 / 64+1 / 128$.
The multiplication to these coefficients can be substituted to the sum of the shifted operands | I | and $|\mathrm{Q}|$, where $|\mathrm{I}|$ - is the absolute value of the two's complement number I. The resulting formula looks like the following:
$\mathrm{A} \approx|\mathrm{I}|-1 / 16^{*}|\mathrm{I}|+1 / 64^{*}|\mathrm{I}|+1 / 128^{*}|\mathrm{I}|+1 / 4^{*}|\mathrm{Q}|+1 / 8^{*}|\mathrm{Q}|+1 / 64^{*}|\mathrm{Q}|+1 / 128^{*}|\mathrm{Q}|$,
The function of the complex vector magnitude is described in VHDL as follows

```
function MAGN_APPROX(A, B: INTEGER) return INTEGER is
    variable Re, Im, Tmp, Magn: I NTEGER;
    begin
    Re: =ABS (A);
    I m: =ABS (B) ;
    if Reslm then
                Tmp: =Re; Re: =| m; I m: =Tmp;
    end if;
    Magn: =Re - Re/ \(16+\operatorname{Re} / 64+\operatorname{Re} / 128+1 \mathrm{~m} / 4+\mid \mathrm{m} / 8+1 \mathrm{~m} / 64+1 \mathrm{~m} / 128\);
    return Magn;
    end function;
```

Firstly the absolute values of the operands are calculated and then they are sorted to fall into the first octant of the Cartesian coordinate system i.e. to satisfy $|\mathrm{A}|>|\mathrm{B}|$. Then the Ponselet function is calculated.

## FM Discriminator

There are several ways to demodulate an FM signal. The most common is to use a discriminator. This is composed of an electronic filter which decreases the amplitude of some frequencies relative to others, followed by an AM demodulator. If the filter response changes linearly with frequency, the
final output will be proportional to the input frequency, as desired. Another is to feed the signal into a phase-locked loop and use the error signal as the demodulated signal.

Consider the signal modulated by the Binary Frequency Shift Keying (BFSK). Then the signal frequency is $f=f_{0}-\Delta f / 2$, when the symbol a $o$ is received. and is $f=f_{0}+\Delta f / 2$, when the symbol a 1 is done. where $\Delta \mathrm{fT}_{\mathrm{C}}=1, \mathrm{~T}_{\mathrm{C}}$ is the symbol period. Therefore, the discriminator must measure the difference $\mathrm{f}-\mathrm{f}_{0}$. Consider in the k -th clock cycle we have the sample vector of the signal $\mathbf{A}_{\mathrm{k}-1}=\mathrm{I}_{\mathrm{k}-1}+$ $j \mathrm{Q}_{\mathrm{k}-1}=|\mathrm{A}| \exp (2 \pi \mathrm{ft})$, and in the next cycle it is $\mathbf{A}_{\mathrm{k}}=\mathrm{I}_{\mathrm{k}}+\mathrm{j} \mathrm{Q}_{\mathrm{k}}=|\mathrm{A}| \exp (2 \pi \mathrm{ft}+\phi)$. Then

$$
\sin ((2 \pi \mathrm{ft})+\phi-2 \pi \mathrm{ft})=\sin (\phi)=\left(\mathrm{Q}_{\mathrm{k}} \mathrm{I}_{\mathrm{k}-1}-\mathrm{I}_{\mathrm{k}} \mathrm{Q}_{\mathrm{k}-1}\right) /|\mathrm{A}|,
$$

Here $\phi=\Delta \mathrm{f} \mathrm{T}_{\mathrm{s}} / 2$ is proportional to $\mathrm{f}-\mathrm{f}_{0}$. where $\mathrm{T}_{\mathrm{s}}$ is the sampling frequency. Then the searched frequency shift with the frequency scaling factor K can be found as

$$
\Delta \mathrm{f}=\mathrm{K} \phi=\mathrm{K} \arcsin (\sin (\phi)) \approx \mathrm{K} \sin (\phi)=\mathrm{K}\left(\mathrm{Q}_{\mathrm{k}} \mathrm{I}_{\mathrm{k}-1}-\mathrm{I}_{\mathrm{k}} \mathrm{Q}_{\mathrm{k}-1}\right) /|\mathrm{A}| .
$$

When the signal magnitude is stable, for example, when it is regulated by the proper feedback, then the formula can be simplified:

$$
\Delta \mathrm{f} \approx \mathrm{~K}^{\prime}\left(\mathrm{Q}_{\mathrm{k}} \mathrm{I}_{\mathrm{k}-1}-\mathrm{I}_{\mathrm{k}} \mathrm{Q}_{\mathrm{k}-1}\right) .
$$

The scaling factor $\mathrm{K}^{\prime}$ can be taken into account when the decision is made, which of symbols is thransferred. Therefore, it represents some threshold value and it does not afford the multiplication.

## PM Discriminator

The complex vector phase is usually calculated as $\theta=\varphi \pm \operatorname{arctg}(\mathrm{Q} / \mathrm{I})$, where $\varphi=0 \mid \pm \pi / 2$ depending on the angle quadrant. Both arctangent and division is rather complex operation to perform it in real time by hard hardware volume requirements.

Volder was the first who proposed to caclulate the phase using his algorithm named CORDIC in the 1950's. Moreover, it gives the vector magnitude in parallel with the angle. The CORDIC uses a sequence like successive approximation to reach its results. The key is it does this by adding/subtracting and shifting only.

Suppose we want to rotate a point(X,Y) by an angle $(\theta)$. The coordinates for the new point(Xnew, Ynew) are:

Xnew $=\mathrm{X}^{*} \cos (\theta)-\mathrm{Y}^{*} \sin (\theta)$
Ynew $=\mathrm{Y}^{*} \cos (\theta)+\mathrm{X} * \sin (\theta)$
Or rewritten:
Xnew $/ \cos (\theta)=\mathrm{X}-\mathrm{Y}^{*} \operatorname{tg}(\theta)$
Ynew $/ \cos (\theta)=Y+X * \operatorname{tg}(\theta)$
It is possible to break the angle into small pieces, such that the tangents of these pieces are always a power of 2 . This results in the following equations:

$$
\begin{aligned}
& \mathrm{X}_{\mathrm{i}+1}=\mathrm{P}_{\mathrm{i}}{ }^{*}\left(\mathrm{X}_{\mathrm{i}} \mathrm{Y}_{\mathrm{i}} 2^{-\mathrm{i}}\right) \\
& \mathrm{Y}_{\mathrm{i}+1}=\mathrm{P}_{\mathrm{i}} *\left(\mathrm{Y}_{\mathrm{i}}+\mathrm{X}_{\mathrm{i}} 2^{-i}\right) \\
& \theta_{\mathrm{i}}=\operatorname{arctg}\left(2^{-\mathrm{i}}\right)
\end{aligned}
$$

The $\operatorname{arctg}\left(2^{-\mathrm{i}}\right)$ has to be pre-computed, because the algorithm uses it to approximate the angle. The $P_{i}$ factor can be eliminated from the equations by pre-computing its final result. If we multiply all $P_{i}$ 's together we get the aggregate constant. This is a constant which reaches $0.607 \ldots$

Such an algorithm is fitted to calculate the $\operatorname{arctg}(\mathrm{Q} / \mathrm{I})$ function. For this purpose the initial vector is given as $Y_{0}, X_{0}=$ Q,I. Then $n$ iterations are performed:

$$
\begin{aligned}
& \operatorname{sign} \xi_{\mathrm{i}}=\operatorname{sign} \mathrm{Y}_{\mathrm{i}} ; \\
& \mathrm{Y}_{\mathrm{i}+1}=\mathrm{Y}_{\mathrm{i}}-\xi_{\mathrm{i}} \mathrm{X}_{\mathrm{i}} 2^{-1} ; \\
& \mathrm{X}_{\mathrm{i}+1}=\mathrm{X}_{\mathrm{i}}+\xi_{\mathrm{i}} \xi \mathrm{Y}_{\mathrm{i}} 2^{-1} ; \\
& \theta_{\mathrm{i}+1}=\theta_{\mathrm{i}}+\xi_{\mathrm{i}} \operatorname{arctg}\left(2^{-\mathrm{i}}\right) .
\end{aligned}
$$

Here $\operatorname{sign} \xi_{i}=1$ when $Y_{i}>0$, and -1 when $Y_{i}<0$.

After n steps the results are $\theta_{\mathrm{n}}=\operatorname{arctg}(\mathrm{Q} / \mathrm{I})$ and $\mathrm{X}_{\mathrm{n}}=1 / \mathrm{P}^{*} \sqrt{ }\left(\mathrm{I}^{2}+\mathrm{Q}^{2}\right)$. It is worth to be mentioned that for n steps n correct bits of the result are calculated. For this feature such an algorithm is often named as "digit by digit" algorithm.

Note that I is considered as $\mathrm{I}>0$. When $\mathrm{I}<0$ its absolute value must be calculated, and the resulting angle must be corrected as $\pm \pi-\theta_{\mathrm{n}}$.

In discriminators it is worth to map the full angle $\pm \pi$ into the range $\pm 1$. Therefore, the arctangent constants are stored according to this fact. These coefficients for 16-bit data are represented in the following table

| i | $\operatorname{arctg}\left(2^{-\mathrm{i}}\right) / \pi$ | i | $\operatorname{arctg}\left(2^{-\mathrm{i}}\right) / \pi$ |
| :---: | :---: | :---: | :---: |
| o | 0,01000000000000000 | 8 | 0,00000000010100011 |
| 1 | 0,00100101110010000 | 9 | 0,00000000001010001 |
| 2 | 0,00010011111101101 | 10 | 0,00000000000101000 |
| 3 | 0,00001010001000100 | 11 | 0,00000000000010100 |
| 4 | 0,00000101000101100 | 12 | 0,00000000000001010 |
| 5 | 0,00000010100010111 | 13 | 0,00000000000000101 |
| 6 | 0,00000001010001100 | 14 | 0,00000000000000010 |
| 7 | 0,00000000101000110 | 15 | 0,00000000000000001 |

## 3. Discriminator design example

Consider the example of the discriminator design, which estimates the phase by the CORDIC algorithm. The initial data is of 10 -bit width, the output phase has the bit width 6 .

Due to the fact, that the most significant bit of the result means the coding of wether 1,4 quadrants, or 2,3 quadrants, we must to implement $6-1=5$ algorithm iterations. For these iterations up to 5 additions of the angles are made. Therefore, the angle coefficients must be of $6+] \log _{2} 5[=9$ bit width.

The discriminator is described by the following VHDL entity

```
|ibrary |EEE;
use IEEE.STD_LOGIC 1164.all;
use IEEE.STD-LOGIC`SIGNED.ail:
entity CORDIC̄5 is \overline{port( CLK : in STD_LOGIC;}
    RST: in STD LOGIC;
        EI: in STD [OGIC; -operation enable
        I: in STD_LOGIC_VECTOR(9 downto 0);
        Q : in STD-LOGIC-VECTOR(9 downto 0);
        FI: out STD_LOGTC_VECTOR(5 downto 0) );
end CORDIC5;
architecture BEH of CORDIC5 is
    signal qi,qa,q1,q2,q3,q4,q5:STD_LOGIC_VECTOR(10 downto 0);
    signal ii,ia,i1,i2,i3,i4,i5:STD-LOGIC-VECTOR(10 downto 0);
    signal sq,si,s1,s2,s3,s4,s5:STD``LOGIC; .. sign of Q
    signal f1,f2,f3,f4,f5: STD_LOGIC_VECTOR(8 downto 0);
begin
    RGI:process(CLK,RST) begin .- input data register
        if RST='1' then
                i i <=( others=>'0');
                        qi<=(others=>'0');
        elsif CLK='1' and CLK'event then
                if El='1' then
                                    i i <=| ( g) &l;
                                    qi<=Q(g)&Q;
                end if;
        end if;
    end process;
    .. now we get the absolute value of ।
    i a<=abs(i i );
    sq<=qi(9); .-data signs
    si<=i i (9);
    .-the first iteration
    sq<=qi(9);
    ql<= qi'.'ia when sq='0' else
```

```
i 1<= ia +qii when sq='0' else
    f1<= "001000000"when sq='0' else --angle 45 grad.
    -"001000000";
    --the second iteration
    s 1<=q1(9);
    q2<= q1.SHR(il,"001") when s1='0' else
    Mgl+SHR(il,"OO1");
    i 2<=i1 + SHR(q1,"OO1") when sl'='0' else
        i1.SHR(q1,"001");
    f2<= f1 + "000100101" when s1='0' else .-angle 22,5 grad.
    f1 - "000100101";
    .-the 3-d iteration

        i3.SHR(q1,"011");
    f 4<= f 3 + "000001010" when s 3 ='0' else ..angle 5,5 grad.
        f3 - "000001010";
    --the 5-th iteration
    s 4<=q4(9);
    q5<= q4.-SHR(i1,"100") when s4='0' else
    q4 + SHR(i1,"100");
    i 5<=i4 +SH'R(q1,"1'0") when s4='0' else
        i4.SHR(q1,"100");
    f 5<="010000000" when ia(10 downto 4)=0 and sq='0' else.-angle go grad.
        "110000000" when i a(10 downto 4)=0 and sq='1' else-.angle-go grad.
        f4 + "000000100" when s4='0' else ..angle 2,7 grad.
        f4 - "0000000100";
    process(CLK,RST) begin -. .- Result Register
        if RST=' 1' then
                        FI<=(others=>'0');
            elsif CLK='1' and CLK'event then
                if si='0'then Fl<=f5(8 downto 3);
                -a angles +-90 grad
                else
                if sq='0' then
                        F|<="011111"-f5(8 downto 3)+1; - angles+90+180 grad
                        else
                        F|<="100001"-f5(8 downto 3)-1; .. angle-90-180 grad
                        end if;
                end if;
    end if;
end process;
end BEH;
```

## 4. Laboratory exercise implementation

The discriminator has to be built and tested as in the previous example.
Each exercise variant has a set of parameters, which are numbered by natural numbers. A set of them is derived from the record-book number of the student. Consider 3 last figures $\mathrm{a}_{2}, \mathrm{a}_{1}, \mathrm{a}_{0}$, of the record-book number. Then the variant number is
$N=100 a_{2}+10 a_{1}+a_{0}=2^{9} b_{9}+2^{8} b_{8}+2^{7} \mathrm{~b}_{7}+2^{6} \mathrm{~b}_{6}+2^{5} \mathrm{~b}_{5}+2^{4} \mathrm{~b}_{4}+2^{3} \mathrm{~b}_{3}+2^{2} \mathrm{~b}_{2}+2^{1} \mathrm{~b}_{9}+\mathrm{b}_{0}$,
where $b_{i}$ are the bits of the number N in the binary representation.
The discriminator parameters are input signal bit width Ni and output signal bit width No is selected from the Table 1.

Table 1

| $\mathrm{b}_{2}, \mathrm{~b}_{1}, \mathrm{~b}_{\mathrm{o}}$, | Ni | No |
| :---: | :---: | :---: |
| 000 | 10 | 4 |
| 001 | 10 | 5 |
| 010 | 12 | 6 |
| 011 | 12 | 7 |
| 100 | 14 | 4 |
| 101 | 14 | 5 |
| 110 | 16 | 6 |
| 111 | 16 | 7 |

Discriminator type and testing type are given in the Table 2
Table 2

| $\mathrm{b}_{3}, \mathrm{~b}_{0}$ | Discriminator type | Test signal generator |
| :---: | :---: | :---: |
| 00 | AM Ponselet | Generator from laboratory exercise 1 with the inputs clipped by a meander |
| 01 | FM | Testbench generator in laboratory exercise 3 |
| 10 | PM CORDIC | Generator from laboratory exercise 1 |
| 11 | AM CORDIC | Generator from laboratory exercise 1 with the inputs clipped by a meander |

## Testing

## 5. Laboratory exercise report

The laboratory exercise report must contain:

- Goal of the work,
- Discriminator description,
- VHDL texts,
- Waveforms of testing,
- Conclusions.
